

LINUX - SIMULATOR

STAGES:

- **ABOUT THE PROJECT:** The Linux Simulator project was created to provide a small-scale simulation of the Linux operating system. The initial concept was not to mimic a specific distribution, but rather to capture general characteristics common to most of them —such as a terminal with basic functions, a web browser, and various other features.

- **OBJECTIVES:** The primary goal of this project was to strengthen my foundation in Python programming within the context of cybersecurity. Having studied the language for approximately 4 to 5 months, I developed this project to apply concepts such as OOP (Object-Oriented Programming), functions, and control structures, while also learning how to organize a larger project and build an application with multiple functionalities.

- **FEATURES:** Since the project simulates an operating system, it includes several features: folder management; a web browser (which houses a gaming platform and a calculator); a calendar; a clock (set to Brasília time); and a terminal supporting simple commands, such as ``ls`` for listing directories.

TECHNOLOGIES USED:

- Python 3
- Python Standard Libraries
- Terminal/CLI

- **FUTURE IMPROVEMENTS:** As this is the initial version of the project, future enhancements are planned, such as adding more terminal commands, introducing new applications, improving error handling, and refining the user interface.
